

InstaMuzik

Due: 09/28/2016

Bibek Subedi

UCF Coding Bootcamp

Overview

Create an application that allows users to search music and share it with other users, while also having the freedom to export and create custom playlists. At the moment, there are various services available that allow users to easily access music. However, this freedom also introduces disorganization in how people listen to music because there is new music being released daily and it is difficult to have a personalized music library. The APIs that will be used to search are Spotify, SoundCloud and GrooveShark.

Technologies

1. Angular JS will be the front end framework used for this project to create a simple and intuitive music player with appropriate routing configuration.
2. Express JS will be used as the back end server along with Node JS as the platform.
3. Mongoose JS will be used to model the user information along with the searches and saved music.
